ABSTRACT

The Albemarle Sound area supports the principal striped bass population in North Carolina. Nets were fished during 1984-1986 to characterize and evaluate the Albemarle Sound gill net fishery. Replicate gill nets of 2.5 through 5.5 inches stretched mesh were fished in different locations, to determine impacts on striped bass conservation. Efforts to direct for other species without capturing striped bass were not successful. The summer and fall striped mullet and flounder gill net fisheries, as regulated, should have a minimal impact on striped bass. Recent revisions in the fall fishery for white perch and striped bass have provided for additional striped bass protection without severely reducing the potential harvest of other species. The 3.5 inch net is the predominant gear used by Albemarle Sound fishermen targeting for white perch and striped bass. The 14 inch total length minimum size limit for striped bass and 3.5 inch mesh nets compliment each other. Approximately 70% of the striped bass taken in 3.5 inch mesh are between 14 and 16 inches (TL) and of age groups I+ or II. Catch-per-unit-of-effort (CPUE) data show the continued use of the 3.5 inch net is essential to a multispecies gill net fishery. No changes were recommended for the spring gill net season. A regression equation was developed to determine the striped bass length for which a mesh size is most efficient. Other species captured were enumerated and measured to determine gill net selectivity and efficiency. Other recommendations to the N.C. Marine Fisheries Commission included: (1) conservative use of the October striped bass season proclamation to allow additional growth and reduce spoilage, (2) opening of the striped bass season when the regular gill net season begins to reduce discard, (3) no changes in gill net stretched mesh size, and (4) additional data collection from the late spring gill net fishery is needed to evaluate further protection measures for mature (spawning stock) striped bass.

INTRODUCTION

Declines in the Atlantic coast stocks of striped bass, Morone saxatilis, particularly the Chesapeake stock, began in the early 1970s and have continued into the 1980s. During the same time period, degraded water quality in western Albemarle Sound contributed to the decline of several area fisheries. Reduced harvest, both commercial and recreational, and a perceived decline in production of striped bass (e.g. year class success - juvenile index (Street 1986, ASMFC 1987)) prompted legislative and administrative actions in order to reverse the decline. The Chafee Emergency Striped Bass Amendment (P.L. 96-118), an amendment to The Anadromous Fish Conservation Act (P.L. 89-304), created the Emergency Striped Bass Study program. The objectives of this program were to conduct research to identify factors contributing to the striped bass decline, monitor the stocks, and assess the economic consequences of the decline (ASMFC 1987).

The Striped Bass Fishery Management Plan, prepared in 1981 by the Atlantic State Marine Fisheries Commission (ASMFC) as part of their Interstate Fisheries Management Program (ISFMP), was designed to provide a coordinated framework to speed the recovery of East Coast stocks. Implementation of the "Plan" was mandated by Congress in The Atlantic Striped Bass Conservation Act (PL 98-613) passed in 1985. States not complying with the "Plan" were subject to federal pre-emption and a possible moratorium on striped bass harvest.

The North Carolina Marine Fisheries Commission is responsible for regulating the commercial and recreational harvest of finfish and shellfish in internal coastal waters (joint and coastal waters) and the Territorial Sea of North Carolina. The North Carolina Wildlife Resources Commission is responsible for regulating the recreational harvest of fisheries in joint and inland waters. The two commissions cooperatively manage the fishery resources in joint waters. Meetings and hearings are held annually by the commissions to solicit public input on proposed management actions recommended by their respective agencies. North Carolina instituted the 14 inch total length (TL) minimum size required for internal waters, closed the ocean fishery in 1985, and has been officially found in compliance with the ASMFC Striped Bass Interstate Management Plan.

The commercial fisheries of the Albemarle Sound basin have been extremely important to the economy of the region since colonial times. Gill nets have

been a major gear used in the harvest of North Carolina finfish since the early 1800's. In 1902 the United States Bureau of Fisheries reported that 107,190 gill nets worth \$236,255 were used by North Carolina fishermen (Smith 1907).

Over the last decade principal commercial gears for striped bass have been anchor gill nets in the estuaries and rivers, with beach seines, trawls and most recently drop or sink gill nets in the ocean (Street and Johnson 1977).

Gill nets are the predominant gear used in Albemarle Sound and account for the majority of the landings for several species including striped bass. In addition, striped bass are highly prized sport and food fish receiving heavy fishing pressure from the recreational fishing community.

The overall objective of this project was to collect information on the varied and complex gill net fisheries of the Albemarle region and to evaluate the management options available for a continued fishery with striped bass conservation measures. Data collected during the project were used throughout the regulatory process, which led to; (1) the adoption of the 14 inch TL minimum size limit for striped bass and (2) revisions in the summer and fall gill net season regulations for striped bass conservation. Specific objectives of the gill net project were:

- (1) to evaluate the size, age, and sex of striped bass taken in the existing Albemarle Sound gill net fisheries,
- (2) to evaluate size composition of other commercially important species harvested by gill nets,
- (3) to evaluate the potential for directing gill net effort towards species other than striped bass,
- (4) to evaluate the management options available with respect to the gill net fishery,
- (5) to collect data so that management agencies have a better understanding of the complexity of the Albemarle Sound area gill net fishery.

STUDY AREA

Albemarle Sound, a shallow estuary 60 miles long and 3.5 to 15 miles wide, is characterized by extensive nearshore shoal areas (1.0 to 6.0 feet) which abruptly drop to deeper waters (7.0 to 25.0 feet). The Roanoke and Chowan Rivers are the major tributaries to the Albemarle Sound. These and other tributaries are bordered by extensive gum-cypress swamps. Albemarle Sound and tributaries are further described in Street et al. (1975).

METHODS AND MATERIALS

Replicate 40 and 80 yard anchor gill nets of selected stretched mesh sizes were fished perpendicular to shore in a manner traditional to Albemarle Sound. Fishing was conducted in locations (Figure 1) being utilized by area commercial fishermen.

Both the shoal areas and the deeper channel waters were fished during the study. Nets fished on the shoal areas were classified as; "FIN" = floating inside the shoal area and fishing the entire water column. Nets set outside the shoal areas in deeper water were classified as; (1) "FO" = floating net outside the shoal area, with the net fishing from the surface to the depth of the net in the water column or, (2) "SO" = sink net outside the shoal area, with the lead line resting on the bottom and the net fishing the water column the depth of the net. Replicate nets of specific sizes were fished in different areas (FIN compared to FO or SO) and in different manners in the same areas (FO compared to SO), such that seasonal species utilization of different habitats and different portions of the water column could be documented and used in management decisions.

Areas fished, net placement, stretched mesh sizes, and net length were varied according to seasonal regulations and fisheries. Table 1 contains information on the seasonal fisheries and the gears used during the project. All nets were not fished during the specified times in the plan of work because of purchasing and construction delays. In order to approximate the gears used, area commercial fishermen were contacted relative to net materials and construction techniques. Nets were constructed by two commercial net makers from the Albemarle area. Specifications on twine size, mesh depth, and construction information for gill nets are contained in Table 2. An area commercial fisherman was contracted to fish the nets and collect data with the assistance of Division of Marine Fisheries personnel.

Weather permitting, fishing was conducted for two six-day periods (10 net days) during each month October - May and for two five-day periods (8 net days) each month June - September.

All striped bass collected were counted and, if possible, measured. Some fish could not be measured due to predation by crabs and decomposition. Striped bass were measured fork length (FL) and total length (TL) in millimeters (mm), weighed in kilograms (kg), sexed (Sykes 1958), and scales taken for ageing. Even though measurements of striped bass were taken in

* Net webbing was no. 4 (#104) .33 mm dia. monofilament twine size.

** Webbing used in the 3.75 in X 25 net was no. 6 (#139) .40 dia. monofilament twine size.

*** The standard for net construction is to hang the webbing to the float and lead lines on the one-half basis (200 running yards of webbing in every 100 yards of net constructed) resulting in a hanging coefficient of 0.5. Area fishermen normally use more webbing per net than is required by hanging on the one-half basis, thus enhancing the catchability of the nets. Project nets, in order to approximate area gears, were hung less than one-half.

millimeters, for discussion purposes all metric measures are converted to English units (see Figures 2-28 for corresponding lengths in millimeters and inches). Striped bass were not aged by sex because data presented in Harriss et al. (1985) shows little difference in growth rate between sexes for fish age VI or less.

Gizzard shad and crevalle jack were counted and size range recorded by mesh size. Blue crabs captured in the nets were counted, but not measured. Other species collected were identified and important commercial and recreational species were measured (TL or FL). Flounder less than 11 inches (TL), minimum legal size limit, were noted.

Data contained in length-frequency and year-class distribution figures show relative distribution of specific size and age groups of striped bass for each mesh size. Tables show species composition, number of fish, percent of total catch by net type, length range, and means for specific mesh sizes.

RESULTS AND DISCUSSION

Fall and Summer Striped Mullet Fishery

During September 1984 net fishing began in Pasquotank River with 2.5 inch nets which are primarily set for striped or "jumping" mullet (Mugil cephalus) in the shoal areas of the sound and rivers.

The small mesh 2.5 and 3.0 inch "mullet nets" had been the topic of considerable controversy regarding their potential impact on striped bass less than 14 inches (TL). The N.C. Marine Fisheries Commission under increased pressure to institute striped bass conservation measures had passed a stringent regulation on the use of mullet nets in the fall 1984. Area fishermen appealed this decision and the Commission repealed the regulation replacing it with a compromise measure which requires that mullet nets be attended [15 NCAC 3B .0401(2)] at all times. The attendance provision allows the live release of striped bass taken in this gear. Current regulations also prohibit the sale of striped bass and the possession of fish which are taken by commercial fishing gear during the summer season (June - September). Data collected during September supported the original intent of the "mullet net" regulation by showing that undersize (less than 14 inches TL, age I+) striped bass were captured in sufficient numbers for concern (Figure 2, 100% <14 in). Data collected on other commercially important species taken during this period are presented in Table 3.

Spot	(1) 1	0.4	167	167
Flounder	(2) 2**	0.9	270-275	273
Gizzard shad	(1) 2	0.9	205	205
Total fish	(187) 227	100.0		

* () denotes number of measurable fish

** 2 flounder less than 11 inches (legal limit).

Mullet nets of 2.5 inch stretched mesh were also fished during October - December, 1984. One mullet net was set in a traditional manner floating in the shallow shoal waters nearshore (FIN net). Another net was fished on the bottom in deep water outside the shoal area in a non-traditional manner for mullet nets (SO net). Nets were set in this manner to determine which species utilize the two different habitats and the effectiveness of traditional mullet nets on striped mullet, striped bass and other species. Traditional mullet (FIN) nets were very effective in capturing striped mullet, white perch (Morone americana), striped bass, and spot (Leiostomus xanthurus) (Table 4). Sink (SO) nets were most effective in capturing white perch, spot, and gizzard shad (Dorosoma cepedianum).

Mullet nets of 2.5 and 3.0 inch were fished during October 1985. These nets were set to determine if a difference existed between a floating net set for mullet in shoal waters (FIN) and a floating net set in the deeper outside waters (FO). Floating outside (FO) nets are not effective in capturing mullet, but are efficient in the capture of striped bass Tables 5 and 6. Figures 3, 4 and 5 contain the respective length-frequencies and year classes for striped bass caught in mullet nets during the falls of 1984 and 1985. Most of the striped bass were less than 14 inches total length and were age I+ (18 to 20 months old).

Tables 7 and 8 contain data collected from "mullet nets", 2.5 and 3.0 inch, fished during June - September 1985 and June 1986. These data continue to support the effectiveness of "FIN" nets on striped mullet and the potential impacts on undersize striped bass, therefore regulations which require full-time attendance at these nets does contribute to striped bass conservation efforts. Striped bass year class and length-frequency data for the summer season are contained in Figures 6, 7 and 8. The majority of striped bass captured during the summer were age I+ (14 - 17 months old) and less than 14 inches (TL).

Summer Flounder Fishery

Nets of 5.0 and 5.5 inch stretched mesh, which are primarily set floating inside (FIN) for flounder (Paralichthys sp.), were evaluated to determine impacts on large striped bass during the summer season. Six striped bass were taken in 5.0 inch nets (Table 9) and no striped bass were taken in the 5.5 inch nets (Table 10). These nets did well on flounder, channel catfish (Ictalurus punctatus), and white catfish (Ictalurus catus).

Table 4. Number of fish, percent of total catch, length range, and mean length for commercially important species, caught by 40 yard/2.5 inch stretched mesh "mullet" gill nets (floating inside = FIN, sink outside = SO) fished for 38 net days during October-December 1984, Albemarle Sound, N. C. (Striped bass, flounder and croaker measurements in total length (TL), all other species in fork length (FL).)

Fall Fishery

The minimum legal mesh size for Albemarle Sound during the fall fishing season (October-December) is 3.5 inch. This is the predominant mesh size utilized by area fishermen because it is selective for large to medium white perch and pan size (12-16 inch, age I+) striped bass. Striped bass dominated the catch during the fall of 1984 (Table 11) and was second to gizzard shad (Table 12) in 1985. Figures 9 and 10 contain length-frequency and year class distribution for striped bass taken in 3.5 inch nets during the fall. Due to the large number of striped bass taken in the 12 to 16 inch size range, a portion of the catch was separated by sex and subsampled for age (year class) determination. Subsampling procedures were based on the method of Ketchen (1950) and Harriss et al. (1985). Fish between 14 and 16 inches (TL) comprised 70.5% and 71.4%, respectively, of the fall 1984 and 1985, 3.5 inch net catch. The majority of the striped bass taken during the fall season by 3.5 inch gear are age I+ (18 to 20 months old).

Data presented in Table 12 support area fishermen's efforts, through regulation, to decrease the harvest of striped bass during the fall season and concentrate on white perch by restricting nets from 3.5 inch up to 4.25 inches to sink nets, only, to be used in water depths 10 feet or more. Floating nets (FIN and F0) captured 33% of the striped bass and 29% of the white perch taken during the fall 1985. Therefore, the elimination of the FIN and F0 nets will provide some conservation of striped bass and will allow for the harvest of the more bottom oriented white perch by S0 nets.

Length-frequency and year class distribution of striped bass captured in 3.75 inch nets fished during the fall 1985 are shown in Figure 11. Approximately sixty-five percent of these fish were between 14 and 17 inches (TL) and 67% were age I+. Comparing Tables 12, 13, 14, and 15 for 3.5, 3.75, 4.0, and 4.25 inch nets, respectively, the white perch catch drops significantly in the nets larger than 3.5 inches. Further, comparison of these tables for the fall 1985 season reinforces efforts directed at striped bass conservation by elimination of the FIN and F0 nets. Striped bass length frequency and year class distribution for 4.0 and 4.25 inch nets fished during the fall 1984 and 1985 are presented in Figures 12, 13, 14, and 15. Few fish were captured in these nets during fall 1984 (Tables 16 and 17) and no comparisons could be made because inside and outside net replicates were not fished.

Table 11. Number of fish, percent of total catch, length range, and mean length for commercially important species caught by 80 yard/3.5 inch stretched mesh gill nets fished for 42 net days during October-December 1984, Albemarle Sound, N. C. (Striped bass, flounder and croaker measurements in total length (TL), all other species in fork length (FL).)

<u>Total fish</u>	<u>17</u>	<u>24</u>	<u>41</u>	<u>100.00</u>		

* 1 flounder less than 11 inches (legal limit).

The majority of the striped bass captured during the fall 1984 and 1985 in 4.0, 4.25 and 4.5 inch nets (Figures 12, 13, 14, 15, and 16) were greater than 17 inches (TL) and age II+ (approximately 30 to 32 months old). Table 18 contains information on fish collected from 4.5 inch nets November - December 1985.

Spring Fishery

The spring season (January - May) is a period characterized by extensive spawning migrations into the Albemarle Sound estuary by anadromous fishes; river herring (alewife, Alosa pseudoharengus and blueback herring, Alosa aestivalis), hickory shad (Alosa mediocris), and American shad, (Alosa sapidissima). White perch, striped bass, and catfish also migrate within the estuary to spawning areas. These migrations make all these species extremely susceptible to harvest by gill nets and other commercial gear.

Stretched mesh gill nets floating outside (F0) and sink outside (S0) of 3.0, 3.5, 3.75, 4.0 and 4.5 inch were fished during the spring season 1985 and 1986. Nets of 4.25 inch were fished only during spring 1986. The minimum mesh size allowed during the spring season is 3.0 inch webbing. River herring, which are abundant during the spring, are the target species for these nets. River herring accounted for over 73% of the fish taken in the 3.0 inch mesh (Tables 19 and 20). White perch were second in abundance. When comparing data for striped bass, white perch, and river herring for 1985 and 1986 mean lengths varied less than .4 inches. Figures 17 and 18 contain the striped bass length-frequency and year class distribution for 3.0 inch mesh during the two spring seasons. Striped bass less than 16 inches (TL) of age group II (21-25 months old) comprised the majority of the catch.

Catch and length data for 3.5 inch mesh nets fished during the spring seasons are contained in Tables 21 and 22. River herring, white perch, catfish, gizzard shad, striped mullet, and striped bass dominated the catch. Comparing 1985 and 1986 data, mean lengths for white perch and river herring varied less than .3 inch (FL). The 3.5 inch nets accounted for the majority of the striped bass (N=209) captured during the spring seasons. Length frequency and year class distributions for these fish are presented in Figure 19 and 20. Striped bass between 14 and 17 inches (TL), of age group II dominated the catch. Year class 1984 (age II) fish taken during 1986 appeared to be faster growers, and covered a broader size range than the 1983 year class (age II) fish taken in 1985.

Table 18. Number of fish, percent of total catch, length range, and mean length for important species caught in 80 yard/4.5 inch stretched mesh gill nets (floating outside = F0 and sink outside = S0) fished for 40 net days during November - December 1985, Albemarle Sound, N.C. (Striped bass and flounder measurements in total length (TL), all other species in fork length (FL).)

Tables 23 and 24 contain data on fish collected by 3.75 inch nets during this season. Catfish and gizzard shad were the most abundant species captured in this size gear. White perch constituted a sizeable portion of the catch during 1986. Striped bass of age II, between 15 and 18 inches (TL) comprised the major portion of the catch (Figures 21 and 22).

Information compiled on fish taken in the 4.0 inch nets are presented in Tables 25 and 26. Catfish and gizzard shad dominated the catch. The 4.0 inch nets were second only to the 3.5 inch net in numbers of striped bass taken during the spring season (N=125). The majority of these age II fish were between 15 and 18 inches (Figures 23 and 24). Four in webbing was the smallest mesh to effectively capture striped bass of two different age groups or year classes (71% = age II and 26% = age III).

Nets of 4.25 inch were fished only during the spring of 1986. The majority of the fish taken by these nets were catfish and gizzard shad (Table 27). American shad and striped bass also made up an economically important portion of the catch. Figure 25 illustrates that the majority of the striped bass captured by the 4.25 inch webbing were 16 to 18 inches (TL) and age II. This mesh size was similar to the 4.0 mesh in capturing more than one age group.

Tables 28 and 29 contain harvest data for species from the 4.5 inch nets. Catfish and gizzard shad continued to be the most prevalent species taken by the larger mesh nets. Catches of American shad, as would be expected, increased as mesh size went up. A significant number of striped bass between 18 and 22 inches were taken (Figures 26 and 27) in this mesh size. These fish were from the 1982 and 1983 year classes (age III) captured in 1985 and 1986, respectively. The 4.5 inch was the only mesh which selected fish predominantly of age group III (approximately 33-37 months old).

Data collected during the spring seasons (1985 and 1986) are the most consistent, due to the numbers of fish collected and effort expended; when comparing mesh size selection by species, catch-per-unit of effort (CPUE) and relative percent of catch by mesh size. The spring season data for striped bass collected in 3.0, 3.5, 3.75, 4.0 and 4.5 inch nets were used to estimate the relationship between mesh size and mean total length. Figure 28 shows the regression equation and the closeness of fit of the regression line to the points representing mean total length and mesh size. This regression equation may be used to determine the length for which a mesh size is most efficient. Mean length per mesh in this study was 0.7 to 0.9 inch greater than

* 3 flounder less than 11 inches (legal limit).

calculations made by Trent and Hassler (1968) for male striped bass collected in the Roanoke River. The difference in lengths may be attributable to the hanging coefficients used and/or hydrological conditions and the effect it has on fishing and capture efficiency of gill nets (e.g. fast flowing Roanoke River compared to the slow moving tidally influenced Albemarle Sound.)

Catch-per-unit of effort (CPUE) data by net sizes with similar effort are presented in Table 30. The 3.0 inch net is indeed a "river herring net" with almost one-half the catch being comprised of these fish. White perch and striped mullet were also very important catch components in the 3.0 inch net. The importance of the 3.5 inch net to a multispecies fishery is evident when comparing the CPUE data with other mesh sizes.

SUMMARY AND RECOMMENDATIONS

Approximately thirty percent of the striped bass taken in 3.0 inch nets during the spring season (January - May) were less than 14 inches total length. Many of the undersize striped bass taken January - May could probably be released alive due to the cooler water temperatures. The 3.0 inch herring nets are an economically important part of the early river herring fishery. Therefore, no changes in gill net mesh size are recommended for the spring season.

Data collected during the summer season support the intent of the new summer gill net regulations. The intent of these regulations, which is to allow the harvest of striped mullet and flounder with little or no impact on striped bass, has been accomplished. Striped bass less than 14 inches (TL) are captured on the shoal areas of Albemarle Sound and its tributaries by the 2.5 inch and 3.0 inch "mullet nets" during this period. However, the attendance at all times provision of the "mullet net" regulation allows for the release of these young fish. Additionally, this provision should restrict the majority of this gear use to daylight periods. Young striped bass appear to utilize these shoal areas mainly at night and during the low light periods of dawn and dusk. Strict enforcement of the "mullet net regulation" will further enhance striped bass conservation. "Flounder nets" (5.0 and 5.5 inch) do not appear to be of concern with the present size ranges of striped bass prevalent in Albemarle Sound. Also, larger striped bass of age III and older appear to avoid if possible, the warmer shoal waters where "flounder nets" are

Table 30. Catch per unit of effort (CPUE) for frequently captured commercial species by specific gill net stretched mesh during January-May 1985 and 1986, Albemarle Sound, N.C. (unit of effort = one net day)

Species	Mesh size (inches)			
	3.0 CPUE	3.5 CPUE	4.0 CPUE	4.5 CPUE
Striped bass	0.49	1.05	0.66	0.50
White perch	8.29	2.40	0.32	0.03
Striped mullet	1.83	0.98	0.07	0.00
Catfish	1.61	2.31	3.31	2.06
River herring	48.22	2.73	0.06	0.01
Hickory shad	0.01	0.47	0.12	0.02
American shad	0.01	0.03	0.08	0.40
Gizzard shad	3.92	4.83	3.30	1.64

most productive. Preliminary data on preferred temperatures of striped bass in Chesapeake Bay further support this behavior (Coutant and Benson 1986).

Fall season (October - December) gill net regulations were revised in 1986 as a result of local efforts to extend the striped bass season earlier into the fall. Revisions were intended to direct effort away from schooling striped bass and towards other species, such as white perch and catfish, by fishing the deeper water areas of the sound. These regulations were recommended by the Albemarle Fishermens Association (AFA) and are supported by data collected during this project. The new regulation [15 NCAC 3B .0401(3)] reads as follows: "From October 1 through December 31, no gill net shall be used which has a mesh length less than three and one-half inches in Albemarle Sound and tributaries. Gill nets which have a mesh length three and one-half inches and greater and less than four and one-quarter inches must be sunk to the bottom, set in no less than eight feet of water in the tributaries, ten feet of water in the Sound, and be no more than 35 meshes deep." This regulation allows for conservation of age I+ striped bass throughout the fall season when they are concentrated in surface feeding schools, without severely restricting the harvest of the more bottom oriented white perch, yellow perch (Perca flavescens), croaker (Micropogonias undulatus), weakfish (Cynoscion regalis) and catfish.

The fourteen inch (TL) size limit for striped bass and 3.5 inch minimum mesh size compliment each other well. Approximately 70% of the striped bass taken in 3.5 inch nets during the fall were between 14 and 16 inches (TL). This is also the largest mesh size which will allow the efficient and economical harvest of white perch. Comparing catches of 3.5 inch nets to the other nets fished during the project, it is evident that total gill net landings would be drastically reduced for many commercially important species if further restrictions were placed on the use of this net.

Conservative use of the newly enacted "October striped bass season" proclamation authority would be beneficial for both the fishermen and the fishery. Spoilage rate for striped bass taken in October 1985, with water temperatures near 21.0°C (70°F), was approximately sixteen percent. Reviewing Division of Marine Fisheries data since the mid-seventies it appears that striped bass growth has increased with fish achieving 12 and 14 inches TL at an earlier age (Street and Johnson 1977 and 1981). Therefore, another month of growth will allow more fish to reach the 14 inch TL minimum size and gain additional weight (Street and Johnson 1981).

Area fishermen are concerned by the discard of striped bass which is occurring by allowing the fall gill net season to begin prior to the opening of striped bass season. Approximately 93% of the striped bass taken in 3.5 inch project nets during October 1985 were dead when taken from the nets, therefore, would have been a wasted by-catch of the fishery. Area citizens do not view this as conservation, when one species is destroyed to allow the harvest of others. Many fishermen are requesting that the opening of the fall striped bass season and the gill net season should coincide.

Changing the minimum size limit on striped bass would not conserve these stocks, without a change in the gill net mesh sizes which are allowed in the Albemarle Sound fishery. An increase in gill net mesh size would eliminate the gill net fishery for all species except striped bass, catfish, and American shad.

Data collected during this project support recently adopted regulations by the North Carolina Marine Fisheries Commission which provide for a continued multi-species gill net fishery with striped bass conservation in the Albemarle Sound.

Additionally, a change to a larger mesh size would direct more effort at the larger size classes of striped bass (mature fish) and American shad, stocks of which are also extremely low from a historical perspective (Winslow et al. 1983, and ASMFC 1985). Gill net mesh sizes of 4.5 inches and greater would be utilized in the harvest of sexually mature striped bass. Male striped bass are sexually mature by age III (>18 inches TL), while almost all females mature by age V (>24 inches TL) (Trent and Hassler 1968 and Harriss et al. 1985). Additional information on the late spring gill net fishery for striped bass and American shad is needed to evaluate future protective measures for mature (spawning stock) striped bass.

ACKNOWLEDGMENTS

The completion of this project involved the assistance and advice of many individuals. Special thanks are expressed to: Maggie Harrell and Beth White, gill net construction; Rodney L. Cross, a local commercial fisherman contracted to fish project nets and assist in data collection; Richard Morcum, Gary B. Davis, and Lawrence Hanford, data collection and analysis; Robert C. Harriss, Jr., striped bass aging technique; Harrel Johnson, Sara Winslow, James Kornegay, and Michael W. Street, technical assistance and guidance. Harrel Johnson, Sara Winslow, Michael W. Street, Maury Wolff, and Mike Byerly reviewed the manuscript and provided valuable comments. Diana D. Willis and Suzanne Russell typed the report. Sincere appreciation is expressed to the Albemarle area commercial net suppliers, commercial fishermen, and Marine Fisheries Enforcement Officers inspectors who contributed their time and knowledge.
